MEASURE Evaluation-PIMA in Kenya is funded by USAID through associate award 623-12-000002 and implemented by the Carolina Population Center at the University of North Carolina at Chapel Hill, with Futures Group, ICF International, Management Sciences for Health, and Tulane University. The views expressed in this publication do not necessarily reflect the views of USAID or the United States government.

Message from the Program Manager

Welcome to the 10th issue of the Malaria Surveillance Bulletin produced by Kenya's Malaria Control Unit (MCU). This issue focuses on the first quarter of the financial year 2014/2015—July to September 2014—with key malaria indicators demonstrated using six surveillance core graphs. Due to differences in malaria transmission in the country, the graphs for outpatient confirmed malaria cases and test positivity rates (TRP) are disaggregated into the four malaria epidemiological zones. Tables showing county data for selected malaria indicators, percentage treated, number of malaria cases, and epidemiological zones are also included.

In this period, His Excellency the President of Kenya Uhuru Kenyatta launched the mass net distribution campaign in Migori County on the 8th of September 2014. The first phase of the distribution then commenced in five counties, namely Migori, Kisumu, Siaya, Vihiga, and Homabay. This distribution campaign will continue until 2015. There were 5,842 health workers in the public health sector trained on malaria case management across the country. The distribution of anti-malarials and rapid diagnostic tests also continued in this period. Program staff finalized the cost of the Kenya Malaria Strategy, and this will be shared with the counties in conjunction with the monitoring and evaluation plan in the next quarter.

We hope that you will use these bulletins to help you understand the situation in your transmission area and counties, thereby helping you make decisions. We encourage you to maintain high reporting rates (above 80%) so that your data is representative of your county, and we also encourage you to also do similar analysis with your surveillance and district health information software (DHIS) data at both the county and sub-county levels.

OUTPATIENT CONFIRMED MALARIA CASES

Figure 1a shows the number of outpatient suspected malaria cases that are confirmed to have malaria parasite by microscopy or RDT per 1,000 people residing in Kenya. The graph shows that confirmed cases reduced in August 2014 but picked up in September 2014. In comparison to 2013, the confirmed cases were less.

Figure 1a: Number of Outpatient Confirmed Malaria Cases per 1,000 Population

Sources: DSRU, KNBS Projection 2009 Census

Figure 1b shows the percentage of outpatient suspected malaria cases that are confirmed to have the malaria parasite by microscopy or rapid diagnostic test kits (RDTs) per 1,000 people by the malaria epidemiological zones. Ideally, a rate of less than 1 case per 1,000 people sustained over a 12-month period indicates readiness for the elimination phase. The graphs show a marked reduction of cases in the endemic zone.

OUTPATIENT TPR AMONG THE UNDER 5 YEARS AND ALL AGES

Figure 2a presents the overall outpatient TPR for the under fives and all ages in Kenya. Figure 2b shows the outpatient TPR for the under fives and all ages by the malaria epidemiological zones. The graphs are based on data from the weekly reports of the Diseases Surveillance and Response Unit (DSRU). These graphs show the trends with regard to the percentage of the malaria cases that tested positive against the total number of cases tested for parasites. Note that the TPR has reduced towards the end of the quarter. The cases are slightly higher than the same period last year.

Figure 2a: Outpatient TPR for < 5yrs and all ages

Source: DSRU

Figure 2b show outpatient TPR disaggregated by different epidemiological zones. The patterns show overall reduction of TPR across the epidemiological zones, except the TPR in the seasonal transmission zone where there was slight increase of the TPR in under 5 years towards the end of the quarter.

SUSPECTED MALARIA CASES TESTED WITH PARASITE-BASED TEST

The graph below depicts the percentage of the suspected malaria cases among the outpatients that underwent a laboratory diagnosis over the reporting period. The testing rate (percentage of suspected malaria cases tested using a parasite-based test) has remained stable, slightly above 100%, in this quarter. However, we can't explain the more than 100% TPR. Double counting of tests and patients who are referred for laboratory tests without passing the outpatient clinic could in part explain this observed anomaly (the numerator, or number of outpatient suspected malaria cases that received laboratory testing, was obtained from laboratory register while the denominator, or the number of outpatient suspected malaria cases, is from OPD register). It is noteworthy that during this time there was a distribution of RDTs to health facilities which were received in August.

Figure 3: Percentage of Suspected Malaria Cases Tested with a Parasite-Based Test

COVERAGE FOR OUTPATIENTS TREATED WITH ACT

Kenya has adopted the policy of testing suspected cases of malaria before treatment. The first line anti-malarial for uncomplicated malaria should only be administered to patients who test positively for malaria parasites using a parasite laboratory test. The ability of health facilities to achieve this has been hampered in the past by low coverage of the RDTs or microscopy. Graph 4a shows the percentage of outpatient cases that were treated using artemisinin-based combination therapy (ACT) over the number of confirmed malaria cases (positive parasitological results) expected to be treated with appropriate antimalarial medicines during the reporting period. The graph shows that the proportion for the quarter is lightly above the 100% target line. This is much better than previous years when the proportion was above 300%. This could be attributed to the ongoing health worker trainings that emphasize diagnosis before treatment and potentially impact health worker clinical practice. Low stocks that were experienced during the period could also have resulted in rationing of the few stocks that were available by ensuring only positive cases were treated with ACT.

Figure 4b: Outpatient Cases Treated with ACT as a Proportion of Suspected Malaria Cases

Source: LMIS/DHIS

PERCENTAGE OF COVERAGE WITH OUTPATIENTS TREATED WITH ACTS AND NUMBER OF LLINs DISTRIBUTED

The prevention of malaria in pregnancy involves combination strategies that together are aimed at reducing maternal and perinatal morbidity and mortality occasioned by malaria. The strategies comprise the antenatal care (ANC) package that comprises at least two doses of intermittent preventive treatment for expectant mothers (IPT2) and provision of long lasting insecticide nets (LLINs). The graphs show a reduction of both IPT1 and IPT2 during this quarter. This could be attributed to stock outs of sulphadoxine pyrimethamine at the ANC. This anti-malarial is to be procured by Counties in endemic areas and we do encourage them to use the LMIS housed in the DHIS for quantification of the amounts that are needed so as to avoid stock outs

REPORTING RATES BY DATA SOURCES

MCU derives surveillance monitoring and evaluation data from various routine data reporting systems that includes DHIS, electronic-Integrated Disease Surveillance and Response (IDSR), and the Logistics Management Information System (LMIS). The reporting rates presented in Figure 6 are for DHIS, IDSR, and LMIS and is derived from the number of health facilities that send in monthly reports against the number of health facilities expected to report each month. The e-IDSR data is an average of the weekly data that was reported during the reporting months. Of note is the decreasing reporting rate for the e-IDSR which is attributable to the challenges in the web-based system and the increase in the number of facilities. The DSRU is looking into web-based system to mitigate. Counties are advised to submit a list of functional facilities to the DSRU.

FROM THE COUNTIES

This section provides a general overview in terms of how the counties performed in data collection and reporting for selected malaria indicators as shown in Table 1 in the reporting quarter 4 of 2013–2014. Those with stars have either overtreated or undertreated out patients. We do emphasize that patients are to be tested before being treated wherever there is diagnostic capability. The difference in the number of outpatient confirmed malaria cases and the aggregated patients on ACT could be due to irrational treatment of negative cases and the bundling of lower weight bands to treat older patients (e.g., combining four blister packs of the 6's to treat a patient heavier than 35kg).

Table 1: Malaria Treatment by County
