

Urban-Rural and Poverty-Related Inequalities in Health Status: *Spotlight on Senegal*

Introduction

National surveys contain a wealth of family planning, reproductive health, and maternal and child health indicators. Comparing these indicators across subnational groups, such as urban versus rural populations or by relative poverty, can pinpoint inequalities and gaps in coverage and assist policymakers and program planners in developing more effective and efficient interventions.

In most developing countries, poverty is highly correlated with place of residence; that is, urban households tend to concentrate among the highest-wealth groups, while rural households tend to concentrate among the poor. Thus, any national comparison of the least poor with the most poor tends to compare the bulk of the urban population with the poorest of the rural poor, making it impossible to determine to what degree the findings reflect inequalities by wealth and/or inequalities by geography. The development of separate urban and rural wealth indices provides a way out of this dilemma.

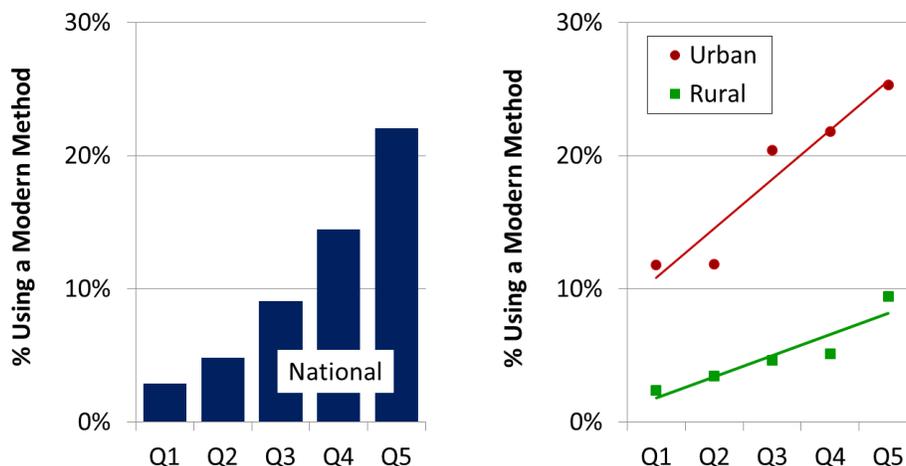

This fact sheet summarizes a few findings from secondary analyses of the Senegal 2005 Demographic and Health Survey (DHS). Separate wealth classifications for urban and rural women were constructed to examine inequalities in key population and reproductive health indicators, including family planning and antenatal care. The analyses demonstrate that disaggregating relative wealth by place of residence may reveal patterns obscured by national trends and the importance of examining multiple indicators.

Findings

Family Planning – National Quintiles vs. Residence-Disaggregated Quintiles

Figure 1 below compares use of modern contraceptives by national wealth quintiles with contraceptive use by urban- and rural-specific wealth quintiles. The wealth-related differentials observed at the national level are seen most clearly among urban women, with similar albeit less pronounced tendencies among rural women.

Figure 1: Poverty-related inequalities in modern contraceptive use

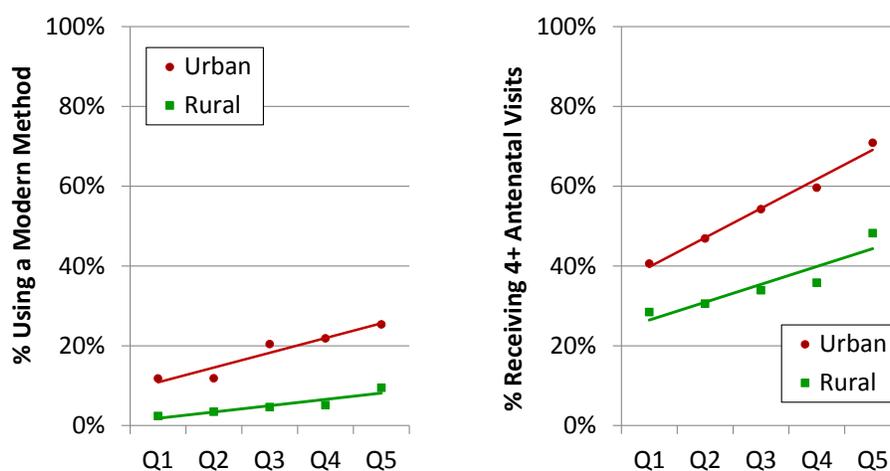

Family Planning vs. Antenatal Care

A potential ambiguity in interpreting differences in family planning is that use is affected not only by access to and ability to pay for modern contraceptives but also by women's interest in and motivation to regulate their fertility. In settings marked by cultural differences and/or variation in educational and economic opportunities for women and girls, it is possible that rural and poorer women want more children than their urban and wealthier counterparts.

Maternity care is a less ambiguous health outcome. Motivation for good outcomes (i.e., healthy mother and healthy child) is unlikely to be subject to cultural factors that may influence family planning. Figure 2 below compares use of modern contraception with adequate antenatal care for the last birth (four or more visits as recommended by WHO and UNICEF). Note that both family planning and antenatal care can be provided in non-clinical settings. While antenatal coverage is higher than family planning use, rural women in general and the poorest urban women fail to meet the Millennium Development Goals target.

Considerations for program design

The findings presented above are only a few of the further analyses that could be conducted with the Senegal 2005 DHS.

- Higher coverage of antenatal care combined with uniformly low family planning use suggests missed opportunities for integration of the two services.
- A generalized strategy for family planning might be indicated, especially in rural areas and possibly in urban areas as well.
- Piloting of focused pro-poor antenatal interventions for the urban poor might be considered.
- Given the generally low antenatal coverage of rural women, more information is needed before deciding on targeted versus generalized rural maternal and child health strategies.
